Lung Function and Respiratory Symptoms at 11 Years in Children Born Extremely Preterm: The Epicure Study

PURPOSE OF THE STUDY. More extremely preterm (EP) infants (≤25 weeks’ gestational age) are surviving. What becomes of these children in terms of lung function?

METHODS. This was a national cohort study that involved all infants born at ≤25 completed weeks’ gestation in the United Kingdom and Ireland between March and December 1995 (N = 182). At the age of 11 years, parents completed a questionnaire and the children performed spirometry. Schoolmates born at term matched for age, gender, and ethnic origin served as controls. Current asthma was defined as “use of asthma medication or wheeze in the past 12 months by children with a doctor diagnosis of asthma, or use of asthma medication and wheeze in the past 12 months even if no prior diagnosis of asthma.”

RESULTS. Twice as many EP-born children (25% vs 13%; P < .01) had current asthma. Baseline spirometry was reduced (forced expiratory volume in 1 second [FEV₁] 83% vs 100% of predicted; P < .001) and bronchodilator responsiveness (≥12% increase in FEV₁) was increased (27% vs 8%; P < .001) in EP-born children. These changes were most marked in those with previous bronchopulmonary dysplasia. Fifty-six percent of EP-born children had abnormal baseline spirometry results, but fewer than half of them were receiving any medication.

CONCLUSIONS. Extreme preterm birth (23–27 weeks’ gestation) but not later preterm birth is associated with an increased risk of asthma, at least in young adulthood.

DIAGNOSIS AND MANAGEMENT

Changing Trends in Asthma in 9–12 Year Olds Between 1964 and 2009

PURPOSE OF THE STUDY. This study is a continuation of the Aberdeen Schools Asthma Survey; the first survey was completed in 1964. Subsequent surveys were repeated in 1989, 1994, 1999, and 2004. This survey reports lifetime prevalence of asthma, eczema, hay fever, and wheeze in the previous 3 years. Trends over a 10-year period (1999, 2004, and 2009) were analyzed.

STUDY POPULATION. Children aged 9 to 12 years in Aberdeen, United Kingdom, were invited to participate in this study.

METHODS. Questionnaires were distributed to children by school staff, completed by parents at home, returned to school staff, and then collected by the research team. The same questionnaire that was used in 2004 was used for this study. In addition, International Study of Allergy and Asthma in Children (ISAAC) questions were included.

RESULTS. A total of 2253 children were eligible for the study, and 1196 (53%) of the surveys were returned. The average age of the children was 10.8 years, and 588 (49%) of them were male. Of 31 eligible primary schools, 26 participated in the study. The number of schools that participated was similar to the number that participated...
