ABSTRACT. The ability to provide life support to ill children who, not long ago, would have died despite medicine's best efforts challenges pediatricians and families to address profound moral questions. Our society has been divided about extending the life of some patients, especially newborns and older infants with severe disabilities. The American Academy of Pediatrics (AAP) supports individualized decision making about life-sustaining medical treatment for all children, regardless of age. These decisions should be jointly made by physicians and parents, unless good reasons require invoking established child protective services to contravene parental authority. At this time, resource allocation (rationing) decisions about which children should receive intensive care resources should be made clear and explicit in public policy, rather than be made at the bedside.

Since the advent of means for supporting newborns with respiratory distress, neonatal and pediatric intensive care has helped tens of thousands of children survive life-threatening illness and the rigors of major surgical intervention. For more than a decade, however, many responsible for the health care of children have debated the appropriateness of applying life-sustaining medical technology (LSMT) to all critically ill children. (The term LSMT here applies to methods of supporting life typically applied in intensive care units, such as the use of ventilators and mechanical or pharmacologic support of circulation. The term critically ill here refers to disorders requiring such LSMT. Both terms defy precise definition.) As a recent AAP policy statement on forgoing LSMT notes, the value of such therapy may be uncertain, especially when first considered. Good medical practice may favor initiation of LSMT until clarification of the clinical situation and relevant ethical values can occur. Much discussion has focused on highly visible "selective nontreatment of handicapped infants" and the responses of the federal government, now colloquially as the "Baby Doe" rules. In the last few years, clinicians and the public also have become increasingly concerned about the high costs, in terms of money, time, and psychosocial consequences, of neonatal and pediatric intensive care.

NEWBORNS AND INFANTS

Much controversy has surrounded the treatment of newborns and older infants with readily identified medical problems, including genetic disorders, malformations and deformations, and, to some extent, extreme prematurity and/or low birth weight. Scientific understanding and improved technology have permitted reductions in mortality for infants affected by an enlarging list of conditions. A better appreciation of what can be done to help many infants with disabilities and social considerations of fairness have led to the application of life-saving medical interventions to critically ill newborns and infants who, not long ago, physicians might not have treated vigorously. Concern that some infants, for example, those with Down syndrome and gastrointestinal obstruction, received insufficient treatment led to the federal legislation (the 1984 Child Abuse Amendments) and regulations that sought to ensure appropriate medical therapy for all disabled infants.

Looking back, the measures to prevent undue discrimination against disabled infants seem to have produced at least two unintended consequences. First, it seems that many persons in the health care and child advocacy professions, along with the general public, misunderstand the various federal and other legal requirements regarding treatment decisions about infants with critical illnesses. Thus, misconceptions about the Baby Doe rules may have become de facto benchmarks for treatment decisions about critically ill newborns and older infants. Second, attention concentrated on saving the lives of infants, some with permanent, severe disabilities or neurodegenerative disorders, has hampered sufficient attention to the possible overuse of LSMT.

With regard to the first point, the actual language of the 1984 Child Abuse Amendments may permit more physician discretion than some realize. Although the law mandates provision of LSMT to most seriously ill infants, it does provide for exceptions in the case of permanent unconsciousness, "futile" treatment, and "virtually futile" therapy that imposes excessive burdens on the infant. Physicians, with parental agreement, may even forgo giving hydration and nutrition when they think these measures are not "appropriate." (Quoted words and phrases come directly from the law.)

With regard to the second point, possible overuse of LSMT, several book-length studies, one personal account from parents, and recent essays by pioneering neonatologists have suggested that modern newborn care may, at times, constitute overtreatment. Articles for the general public have communicated the same message. As previously noted, after the Child Abuse Amendments of 1984, two reports of a survey of neonatologists indicated...
that many who specialize in the care of sick new-
borns believe they are legally constrained to provide
LSMT to infants, even when their medical judgments
and the views of the parents concur that withholding
treatment is preferable.

Although many would like to have simply inter-
preted and easily applied substantive standards for
clinical decisions about critically ill infants, medical
and moral complexity make such rules imprudent.
Scientific uncertainty regarding outcome continues
in the neonatal intensive care unit. Some very tiny
infants with documented brain insults, such as those
that may occur with periventricular hemorrhage,
defy expectations and survive with no apparent clin-
cal deficits. Available evidence, however, continues
to indicate that the decreased mortality brought
about by neonatal intensive care has been accompa-
nied by increased morbidity, i.e., serious mental and
physical limitations among survivors that impose
burdens on affected children and their families.\textsuperscript{18,19}
These factors also play legitimate roles in decision
making.\textsuperscript{20,21}

A few well-publicized cases in the early 1980s led
some to conclude that physicians and parents com-
monly denied beneficial treatment to imperiled new-
borns. However, no reliable evidence that decisions
endangering children have been widespread exists.
Most cases of lethal nontreatment seem to have in-
volved infants with trisomy 21 and myelomeningo-
cele.\textsuperscript{22-24} However, by the early 1980s professional
and public views about infants with Down syn-
drome and spina bifida had generally shifted to fa-
vor treatment.\textsuperscript{25} This view is supported by results
from a survey of pediatricians done in Massachusetts
in the mid-1980s.\textsuperscript{24}

The AAP supports parental involvement in deci-
sions about imperiled infants from the earliest pos-
sible moment. Obstetricians and pediatricians need
to inform and counsel parents about available op-
tions when prenatal diagnostic procedures identify
disorders in fetuses. Women may legitimately decide
about the treatment they and their fetuses receive.\textsuperscript{26,27}
Once parturition occurs, parents continue to have
a vital role in decision making under the assumption
that they accept responsibility for nurturing the in-
fant and providing reasonable care.\textsuperscript{28}

The AAP believes that parents and physicians
should make reasoned decisions together about criti-
cally ill infants using the principles of informed
parental permission recently articulated by the AAP.\textsuperscript{29} Such decisions should consider the benefits
and burdens of treatment alternatives. Physicians
should remember that many parents want a strong
role in these decisions\textsuperscript{30} and that parents may bring
values to the process that differ sharply from those of
the physician. In rare instances, as required by law
and sound ethical standards, it may be necessary to
invoke established child protective mechanisms if
parents wish to forgo LSMT, physicians disagree,
and the parties cannot resolve their differences with
help from subspecialists, ethics consultants, or ethics
committees.

CHILDREN BEYOND INFANCY

As with infants, two basic questions arise in the
care of children beyond the first year: Which values
and whose authority ought to govern in medical
treatment decisions about the critically ill? Published
court cases indicate that parents have been permitted
to exercise broad discretion when acting on their
children’s behalf even when court-appointed
 guardians ad litem or other counsel opposed the
parental choice.\textsuperscript{37-39} Laws in some states permit par-
ents to execute advance directives on behalf of mi-
 nors (Choice and Dying. State laws regarding end-
of-life decision making for minors. New York, NY: Choice and Dying: September 1995:1-2).\textsuperscript{40} In addi-
tion to according due respect to the beliefs, feelings,
and needs of the family as expressed by parents, as
children get older and acquire cognitive skill, expe-
rience, and emotional maturity, their individual
views deserve careful consideration. Sensitive cli-
nicians and parents acknowledged this in the profes-
sional literature as long as 20 years ago.\textsuperscript{41}

In the realm of pediatric critical care, the North-
eric American literature provides sparse evidence of sys-
tematic approaches to limiting LSMT.\textsuperscript{42,43} The pedi-
atriic intensive care unit, however, unlike the neo-
natal intensive care unit, has not been the focus of
bureaucratic or political debate and action. Pediatric
intensivists and their colleagues and consultants in
ethics have tended to make decisions about discon-
tinuing LSMT similar to the way clinicians, loved
ones, ethicists, and the courts make such decisions
for incompetent adult patients.\textsuperscript{34,45}

RESOURCE ALLOCATION AND DECISIONS TO
LIMIT LSMT

Recently, concerns about the high cost of critical
care have led to attempts to manage critical care
resources through the use of quantitative indicators
of prognosis.\textsuperscript{46-51} Some physicians, administrators,
and planners would like to use increasingly accurate
statistical predictors of outcome to exclude patients
from receiving intensive care services. Indeed, pop-
ulation-based mathematical tools may prove helpful
in evaluating the effectiveness of various interven-
tions, in comparing outcomes of similar treatments
used at different sites, and in informing parents of
the probability of the outcome of treatment. Such
studies, however, have an important inherent limi-
tation—their results apply to groups of patients, not
individuals. In the absence of perfect outcome pre-
diction (100% survival or death, based on experience
with large numbers of patients), statistical indicators
cannot tell clinicians which particular patient will die
or live (and with what residual problems). Moreover,
even overwhelming odds of success or failure of
treatment cannot take into account the complex val-
ues that individuals, including patients, family mem-
bers, physicians, and other health care providers,
bring to a treatment decision. Therefore, the AAP
opposes the use of these formulas as the principal
determinants of whether individual patients receive
intensive care.

The controversy over the usefulness of critical care
resources has been most poignantly highlighted by public debates about futile medical treatment. In these discussions, physicians and other care givers have demonstrated concern that medical resources are being used inappropriately and that continued treatment violates deeply held beliefs about what properly constitutes professional activities. Others feel that professional objections to so-called futile treatment masks prejudices about those who are disabled, who come from disadvantaged social groups, or who are dying.

The AAP thinks that judgments about which diagnostic categories of patients should receive or be denied intensive care based on considerations of resource use are social policy deliberations and should be made after considerable public discussion, not ad hoc at the bedside.

CONCLUSIONS

Our society has reached a consensus that some critically ill infants previously denied treatment should receive advanced medical and surgical care. A large majority of physicians and other persons agree that most infants with Down syndrome with gastrointestinal obstruction and most infants with myelomeningocele should have surgery and other treatment they need.

There is less agreement, however, about how much treatment to provide other critically ill infants and children. Medical and public controversy still rages about the appropriate limits, if any, to place on the treatment of extremely low birth weight and premature infants, about infants with hypoplastic left heart syndrome, about children with chromosomal abnormalities with known very limited life spans, about infants with complex congenital abnormalities, and about children in the final stages of terminal cancer or other fatal chronic disorders. Many think that laws, regulations, and government policies have unduly constrained parents and physicians from exercising reasonable judgments about whether to forgo LSMT.

A judicial and legislative consensus has developed that the values of patients, rather than those of physicians or policy makers, should determine the extent of the application of LSMT. As noted, some states have empowered proxy decision makers to execute advance directives regarding LSMT on behalf of minors. Legislation and regulation about disabled infants conflict with the legal trends governing all other patients. In the absence of compelling evidence that infants require special legal protection, the AAP thinks that parents of newborns should have the same decision-making authority they have with older children.

Limited resources may require equitable limits on medical treatment. Such restrictions require careful consideration of their social, cultural, and economic consequences and deserve to be made at a public policy level, not at the bedside.

RECOMMENDATIONS

1. Decisions about critical care for newborns, infants, and children should be made similarly and with informed parental permission.
2. Physicians should recommend the provision or forgoing of critical care services based on the projected benefits and burdens of treatment, recognizing that parents may perceive and value these benefits and burdens differently from medical professionals.
3. Decisions to forgo critical care services on the grounds of resource limitations, generally speaking, are not clinical decisions, and physicians should avoid such “bedside rationing.”

However, because many in the American public think that our health care system spends excessively on critical care services, society should engage in a thoroughgoing debate about the economic, cultural, religious, social, and moral consequences of imposing limits on which patients should receive intensive care.
