SIDS and Other Sleep-Related Infant Deaths: Updated 2016 Recommendations for a Safe Infant Sleeping Environment

BACKGROUND

Sudden unexpected infant death (SUID), also known as sudden unexpected death in infancy, or SUDI, is a term used to describe any sudden and unexpected death, whether explained or unexplained.
and trauma (unintentional or associated cardiac channelopathies, entrapment, infection, ingestions, attributed to suffocation, asphyxia, after case investigation, SUID can be deaths), occurring during infancy. syndrome [SIDS] and ill-defined (including sudden infant death syndrome, SIDS): Cause assigned to infant deaths that cannot be explained after a thorough case investigation, including a scene investigation, autopsy, and review of the clinical history.2 Sudden unexpected infant death (SUID), or sudden unexpected death in infancy (SUDI): A sudden and unexpected death, whether explained or unexplained (including SIDS), occurring during infancy.

### Table 1 Definitions of Terms

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bed-sharing</td>
<td>Parent(s) and infant sleeping together on any surface (bed, couch, chair).</td>
</tr>
<tr>
<td>Caregivers</td>
<td>Throughout the document, “parents” are used, but this term is meant to indicate any infant caregivers.</td>
</tr>
<tr>
<td>Cosleeping</td>
<td>This term is commonly used, but the task force finds it confusing, and it is not used in this document. When used, authors need to make clear whether they are referring to sleeping in close proximity (which does not necessarily entail bed-sharing) or bed-sharing.</td>
</tr>
<tr>
<td>Room-sharing</td>
<td>Parent(s) and infant sleeping in the same room on separate surfaces.</td>
</tr>
<tr>
<td>Sleep-related infant death: SUID that occurs during an observed or unobserved sleep period.</td>
<td></td>
</tr>
<tr>
<td>Sudden infant death syndrome (SIDS): Cause assigned to infant deaths that cannot be explained after a thorough case investigation, including a scene investigation, autopsy, and review of the clinical history.2</td>
<td></td>

<table>
<thead>
<tr>
<th>Level</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>A-level</td>
<td>Back to sleep for every sleep. Use a firm sleep surface. Breastfeeding is recommended. Room-sharing with the infant on a separate sleep surface is recommended. Keep soft objects and loose bedding away from the infant’s sleep area. Consider offering a pacifier at naptime and bedtime. Avoid smoke exposure during pregnancy and after birth. Avoid alcohol and illicit drug use during pregnancy and after birth. Avoid overheating. Pregnant women should seek and obtain regular prenatal care. Infants should be immunized in accordance with AAP and CDC recommendations. Do not use home cardiorespiratory monitors as a strategy to reduce the risk of SIDS. Health care providers, staff in newborn nurseries and NICUs, and child care providers should endorse and model the SIDS risk-reduction recommendations from birth. Media and manufacturers should follow safe sleep guidelines in their messaging and advertising. Continue the “Safe to Sleep” campaign, focusing on ways to reduce the risk of all sleep-related infant deaths, including SIDS, suffocation, and other unintentional deaths. Pediatricians and other primary care providers should actively participate in this campaign.</td>
</tr>
<tr>
<td>B-level</td>
<td>Avoid the use of commercial devices that are inconsistent with safe sleep recommendations. Supervised, awake tummy time is recommended to facilitate development and to minimize development of positional plagiocephaly.</td>
</tr>
<tr>
<td>C-level</td>
<td>Continue research and surveillance on the risk factors, causes, and pathophysiologic mechanisms of SIDS and other sleep-related infant deaths, with the ultimate goal of eliminating these deaths entirely. There is no evidence to recommend swaddling as a strategy to reduce the risk of SIDS.</td>
</tr>
</tbody>
</table>

The following levels are based on the Strength-Of-Recommendation Taxonomy (SORT) for the assignment of letter grades to each of its recommendations (A, B, or C).2 Level A: There is good-quality patient-oriented evidence. Level B: There is inconsistent or limited-quality patient-oriented evidence. Level C: The recommendation is based on consensus, disease-oriented evidence, usual practice, expert opinion, or case series for studies of diagnosis, treatment, prevention, or screening. Note: “patient-oriented evidence” measures outcomes that matter to patients: morbidity, mortality, symptom improvement, cost reduction, and quality of life; “disease-oriented evidence” measures immediate, physiologic, or surrogate endpoints that may or may not reflect improvements in patient outcomes (e.g., blood pressure, blood chemistry, physiologic function, pathologic findings). CDC, Centers for Disease Control and Prevention.

The recommendations outlined herein were developed to reduce the risk of SIDS and sleep-related suffocation, asphyxia, and entrapment among infants in the general population. As defined by epidemiologists, risk refers to the probability that an outcome will occur given the presence of a particular factor or set of factors. Although all 19 recommendations are directed toward infants, some recommendations are also directed toward health providers and professionals who care for or work on behalf of infants. In addition, because certain behaviors, such as smoking, can increase risk for the infant, some recommendations are directed toward women who are pregnant or may become pregnant in the near future.

Table 2 summarizes each recommendation and provides the strength of the recommendation, which is based on the Strength-Of-Recommendation Taxonomy.2 It should be noted that there are no randomized controlled trials with regard to SIDS and other sleep-related deaths; instead, case-control studies are the standard. The recommendations are based on epidemiologic studies that include infants up to 1 year of age. Therefore, recommendations for sleep position and the sleep environment, unless otherwise specified, are for the first year after birth. The evidence-based recommendations that

**TABLE 2** Summary of Recommendations With Strength of Recommendation

A-level recommendations
- Back to sleep for every sleep.
- Use a firm sleep surface.
- Breastfeeding is recommended.
- Room-sharing with the infant on a separate sleep surface is recommended.
- Keep soft objects and loose bedding away from the infant’s sleep area.
- Consider offering a pacifier at naptime and bedtime.
- Avoid smoke exposure during pregnancy and after birth.
- Avoid alcohol and illicit drug use during pregnancy and after birth.
- Avoid overheating.
- Pregnant women should seek and obtain regular prenatal care.
- Infants should be immunized in accordance with AAP and CDC recommendations.
- Do not use home cardiorespiratory monitors as a strategy to reduce the risk of SIDS.
- Health care providers, staff in newborn nurseries and NICUs, and child care providers should endorse and model the SIDS risk-reduction recommendations from birth.
- Media and manufacturers should follow safe sleep guidelines in their messaging and advertising.
- Continue the “Safe to Sleep” campaign, focusing on ways to reduce the risk of all sleep-related infant deaths, including SIDS, suffocation, and other unintentional deaths. Pediatricians and other primary care providers should actively participate in this campaign.

B-level recommendations
- Avoid the use of commercial devices that are inconsistent with safe sleep recommendations.
- Supervised, awake tummy time is recommended to facilitate development and to minimize development of positional plagiocephaly.

C-level recommendations
- Continue research and surveillance on the risk factors, causes, and pathophysiologic mechanisms of SIDS and other sleep-related infant deaths, with the ultimate goal of eliminating these deaths entirely.
- There is no evidence to recommend swaddling as a strategy to reduce the risk of SIDS.

The following levels are based on the Strength-Of-Recommendation Taxonomy (SORT) for the assignment of letter grades to each of its recommendations (A, B, or C).2 Level A: There is good-quality patient-oriented evidence. Level B: There is inconsistent or limited-quality patient-oriented evidence. Level C: The recommendation is based on consensus, disease-oriented evidence, usual practice, expert opinion, or case series for studies of diagnosis, treatment, prevention, or screening. Note: “patient-oriented evidence” measures outcomes that matter to patients: morbidity, mortality, symptom improvement, cost reduction, and quality of life; “disease-oriented evidence” measures immediate, physiologic, or surrogate endpoints that may or may not reflect improvements in patient outcomes (e.g., blood pressure, blood chemistry, physiologic function, pathologic findings). CDC, Centers for Disease Control and Prevention.

The recommendations outlined herein were developed to reduce the risk of SIDS and sleep-related suffocation, asphyxia, and entrapment among infants in the general population. As defined by epidemiologists, risk refers to the probability that an outcome will occur given the presence of a particular factor or set of factors. Although all 19 recommendations are directed toward infants, some recommendations are also directed toward health professionals who care for or work on behalf of infants. In addition, because certain behaviors, such as smoking, can increase risk for the infant, some recommendations are directed toward women who are pregnant or may become pregnant in the near future.

Table 2 summarizes each recommendation and provides the strength of the recommendation, which is based on the Strength-Of-Recommendation Taxonomy.2 It should be noted that there are no randomized controlled trials with regard to SIDS and other sleep-related deaths; instead, case-control studies are the standard. The recommendations are based on epidemiologic studies that include infants up to 1 year of age. Therefore, recommendations for sleep position and the sleep environment, unless otherwise specified, are for the first year after birth. The evidence-based recommendations that
follow are provided to guide health
care providers in conversations
with parents and others who care
for infants. Health care providers
are encouraged to have open and
nonjudgmental conversations with
families about their sleep practices.
Individual medical conditions may
warrant that a health care provider
recommend otherwise after weighing
the relative risks and benefits.
For the background literature
review and data analyses on
which this policy statement and
recommendations are based, refer to
the accompanying technical report,
“SIDS and Other Sleep-Related Infant
Deaths: Evidence Base for 2016
Updated Recommendations for a
Safe Infant Sleeping Environment,”
available in the electronic pages of
this issue (www.pediatrics.org/cgi/
doi/10.1542/peds.2016-2940).³

RECOMMENDATIONS TO REDUCE THE
RISK OF SIDS AND OTHER SLEEP-
RELATED INFANT DEATHS

1. Back to sleep for every sleep.

To reduce the risk of SIDS, infants
should be placed for sleep in a supine
position (wholly on the back) for
every sleep by every caregiver until
the child reaches 1 year of age.⁴⁻⁸
Side sleeping is not safe and is not
advised.⁵⁻⁷

The supine sleep position does not
increase the risk of choking and
aspiration in infants, even those with
gastroesophageal reflux, because
infants have airway anatomy and
mechanisms that protect against
aspiration.⁹⁻¹⁰ The American Academy
of Pediatrics (AAP) concurs with the
North American Society for Pediatric
Gastroenterology and Nutrition
that “the risk of SIDS outweighs
the benefit of prone or lateral sleep
position on GER [gastroesophageal
reflux]; therefore, in most infants
from birth to 12 months of age,
supine positioning during sleep is
recommended. …Therefore, prone
positioning is acceptable if the infant
is observed and awake, particularly
in the postprandial period, but
prone positioning during sleep can
only be considered in infants with
certain upper airway disorders
in which the risk of death from
GERD [gastroesophageal reflux
disease] may outweigh the risk of
SIDS.”¹¹ Examples of such upper
airway disorders are those in which
airway-protective mechanisms are
impaired, including infants with
anatomic abnormalities, such as type
3 or 4 laryngeal clefts, who have not
undergone antireflux surgery. There
is no evidence to suggest that infants
receiving nasogastric or orogastric
feeds are at an increased risk of
aspiration if placed in the supine
position. Elevating the head of the
infant’s crib is ineffective in reducing
gastroesophageal reflux¹² and is not
recommended; in addition, elevating
the head of the crib may result in the
infant sliding to the foot of the crib
into a position that may compromise
respiration.

Preterm infants should be placed
supine as soon as possible. Preterm
infants are at increased risk of
SIDS¹³,¹⁴ and the association
between prone sleep position and
SIDS among low birth weight and
preterm infants is equal to, or
perhaps even stronger than, the
association among those born at
term.¹⁵ The task force concurs with
the AAP Committee on Fetus and
Newborn that “preterm infants
should be placed supine for sleeping,
just as term infants should, and the
parents of preterm infants should
be counseled about the importance
of supine sleeping in preventing
SIDS. Hospitalized preterm infants
should be kept predominantly in
the supine position, at least from
the postmenstrual age of 32 weeks
onward, so that they become
acclimated to supine sleeping before
discharge.”¹⁶ NICU personnel should
endorse safe sleeping guidelines with
parents of infants from the time of
admission to the NICU.

As stated in the AAP clinical report,
“skin-to-skin care is recommended
for all mothers and newborns,
regardless of feeding or delivery
method, immediately following birth
(as soon as the mother is medically
stable, awake, and able to respond
to her newborn), and to continue for at
least an hour.”¹⁷ Thereafter, or when
the mother needs to sleep or take
care of other needs, infants should be
placed supine in a bassinet. There is
no evidence that placing infants on
their side during the first few hours
after delivery promotes clearance of
amniotic fluid and decreases the risk
of aspiration. Infants in the newborn
nursery and infants who are rooming
in with their parents should be
placed in the supine position as soon
as they are ready to be placed in the
bassinet.

Although data to make specific
recommendations as to when it is
safe for infants to sleep in the prone
or side position are lacking, studies
establishing prone and side sleeping
as risk factors for SIDS include
infants up to 1 year of age. Therefore,
the best evidence suggests that
infants should continue to be placed
supine until 1 year of age. Once an
infant can roll from supine to prone
and from prone to supine, the infant
can be allowed to remain in the sleep
position that he or she assumes.
Because rolling into soft bedding is
an important risk factor for SUID
after 3 months of age,¹⁸ parents and
caregivers should continue to keep
the infant’s sleep environment clear
of soft or loose bedding.

2. Use a firm sleep surface.

Infants should be placed on a firm
sleep surface (e.g., mattress in a
safety-approved crib) covered by a
fitted sheet with no other bedding or
soft objects to reduce the risk of SIDS
and suffocation.

A firm surface maintains its shape
and will not indent or conform to
the shape of the infant’s head when
the infant is placed on the surface.

As stated in the AAP clinical report,
“skin-to-skin care is recommended
for all mothers and newborns,
regardless of feeding or delivery
method, immediately following birth
(as soon as the mother is medically
stable, awake, and able to respond
to her newborn), and to continue for at
least an hour.”¹⁷ Thereafter, or when
the mother needs to sleep or take
care of other needs, infants should be
placed supine in a bassinet. There is
no evidence that placing infants on
their side during the first few hours
after delivery promotes clearance of
amniotic fluid and decreases the risk
of aspiration. Infants in the newborn
nursery and infants who are rooming
in with their parents should be
placed in the supine position as soon
as they are ready to be placed in the
bassinet.

Although data to make specific
recommendations as to when it is
safe for infants to sleep in the prone
or side position are lacking, studies
establishing prone and side sleeping
as risk factors for SIDS include
infants up to 1 year of age. Therefore,
the best evidence suggests that
infants should continue to be placed
supine until 1 year of age. Once an
infant can roll from supine to prone
and from prone to supine, the infant
can be allowed to remain in the sleep
position that he or she assumes.
Because rolling into soft bedding is
an important risk factor for SUID
after 3 months of age,¹⁸ parents and
caregivers should continue to keep
the infant’s sleep environment clear
of soft or loose bedding.

2. Use a firm sleep surface.

Infants should be placed on a firm
sleep surface (e.g., mattress in a
safety-approved crib) covered by a
fitted sheet with no other bedding or
soft objects to reduce the risk of SIDS
and suffocation.

A firm surface maintains its shape
and will not indent or conform to
the shape of the infant’s head when
the infant is placed on the surface.
Soft mattresses, including those made from memory foam, could create a pocket (or indentation) and increase the chance of rebreathing or suffocation if the infant is placed in or rolls over to the prone position.\textsuperscript{19,20} A crib, bassinet, portable crib, or play yard that conforms to the safety standards of the Consumer Product Safety Commission (CPSC), including those for slat spacing less than 2-3/8 inches, snugly fitting and firm mattresses, and no drop sides, is recommended.\textsuperscript{21} In addition, parents and providers should check to make sure that the product has not been recalled. This is particularly important for used cribs. Cribs with missing hardware should not be used, nor should the parent or provider attempt to fix broken components of a crib, because many deaths are associated with cribs that are broken or with missing parts (including those that have presumably been fixed). Local organizations throughout the United States can help to provide low-cost or free cribs or play yards for families with financial constraints.

Bedside sleepers are attached to the side of the parental bed. The CPSC has published safety standards for these products,\textsuperscript{22} and they may be considered by some parents as an option. However, there are no CPSC safety standards for in-bed sleepers. The task force cannot make a recommendation for or against the use of either bedside sleepers or in-bed sleepers, because there have been no studies examining the association between these products and SIDS or unintentional injury and death, including suffocation.

Only mattresses designed for the specific product should be used. Mattresses should be firm and should maintain their shape even when the fitted sheet designated for that model is used, such that there are no gaps between the mattress and the wall of the crib, bassinet, portable crib, or play yard. Pillows or cushions should not be used as substitutes for mattresses or in addition to a mattress. Mattress toppers, designed to make the sleep surface softer, should not be used for infants younger than 1 year.

There is no evidence that special crib mattresses and sleep surfaces that claim to reduce the chance of rebreathing carbon dioxide when the infant is in the prone position reduce the risk of SIDS. However, there is no disadvantage to the use of these mattresses if they meet the safety standards as described previously. Soft materials or objects, such as pillows, quilts, comforters, or sheepskins, even if covered by a sheet, should not be placed under a sleeping infant. If a mattress cover to protect against wetness is used, it should be tightly fitting and thin.

Infants should not be placed for sleep on beds, because of the risk of entrapment and suffocation.\textsuperscript{23,24} In addition, portable bed rails should not be used with infants, because of the risk of entrapment and strangulation.

The infant should sleep in an area free of hazards, such as dangling cords, electric wires, and window-covering cords, because these may present a strangulation risk.

Sitting devices, such as car seats, strollers, swings, infant carriers, and infant slings, are not recommended for routine sleep in the hospital or at home, particularly for young infants.\textsuperscript{25-30} Infants who are younger than 4 months are particularly at risk, because they may assume positions that can create a risk of suffocation or airway obstruction or may not be able to move out of a potentially asphyxiating situation. When infant slings and cloth carriers are used for carrying, it is important to ensure that the infant’s head is up and above the fabric, the face is visible, and the nose and mouth are clear of obstructions.\textsuperscript{31} After nursing, the infant should be repositioned in the sling so that the head is up, is clear of fabric, and is not against the adult’s body or the sling. If an infant falls asleep in a sitting device, he or she should be removed from the product and moved to a crib or other appropriate flat surface as soon as is safe and practical. Car seats and similar products are not stable on a crib mattress or other elevated surfaces.\textsuperscript{32-36} Infants should not be left unattended in car seats and similar products, nor should they be placed or left in car seats and similar products with the straps unbuckled or partially buckled.\textsuperscript{30}

3. Breastfeeding is recommended.

Breastfeeding is associated with a reduced risk of SIDS.\textsuperscript{37-39} Unless contraindicated, mothers should breastfeed exclusively or feed with expressed milk (ie, not offer any formula or other nonhuman milk-based supplements) for 6 months, in alignment with recommendations of the AAP.\textsuperscript{40}

The protective effect of breastfeeding increases with exclusivity.\textsuperscript{39} However, any breastfeeding has been shown to be more protective against SIDS than no breastfeeding.\textsuperscript{39}

4. It is recommended that infants sleep in the parents’ room, close to the parents’ bed, but on a separate surface designed for infants, ideally for the first year of life, but at least for the first 6 months.

There is evidence that sleeping in the parents’ room but on a separate surface decreases the risk of SIDS by as much as 50%.\textsuperscript{5,8,41,42} In addition, this arrangement is most likely to prevent suffocation, strangulation, and entrapment that may occur when the infant is sleeping in the adult bed.

The infant’s crib, portable crib, play yard, or bassinet should be placed in the parents’ bedroom until the child’s first birthday. Although there is no specific evidence for moving an infant to his or her own room before 1 year of age, the first 6 months are particularly critical, because
the rates of SIDS and other sleep-related deaths, particularly those occurring in bed-sharing situations, are highest in the first 6 months. Placing the crib close to the parents’ bed so that the infant is within view and reach can facilitate feeding, comforting, and monitoring of the infant. Room-sharing reduces SIDS risk and removes the possibility of suffocation, strangulation, and entrapment that may occur when the infant is sleeping in the adult bed.

There is insufficient evidence to recommend for or against the use of devices promoted to make bed-sharing “safe.” There is no evidence that these devices reduce the risk of SIDS or suffocation or are safe. Some products designed for in-bed use (in-bed sleepers) are currently under study but results are not yet available. Bedside sleepers, which attach to the side of the parental bed and for which the CPSC has published standards, may be considered by some parents as an option. There are no CPSC safety standards for in-bed sleepers. The task force cannot make a recommendation for or against the use of either bedside sleepers or in-bed sleepers, because there have been no studies examining the association between these products and SIDS or unintentional injury and death, including suffocation.

Infants who are brought into the bed for feeding or comforting should be returned to their own crib or bassinet when the parent is ready to return to sleep.7,43

Couches and armchairs are extremely dangerous places for infants. Sleeping on couches and armchairs places infants at extraordinarily high risk of infant death, including SIDS, suffocation through entrapment or wedging between seat cushions, or overlay if another person is also sharing this surface.44 Therefore, parents and other caregivers should be especially vigilant as to their wakefulness when feeding infants or lying with infants on these surfaces. Infants should never be placed on a couch or armchair for sleep.

The safest place for an infant to sleep is on a separate sleep surface designed for infants close to the parents’ bed. However, the AAP acknowledges that parents frequently fall asleep while feeding the infant. Evidence suggests that it is less hazardous to fall asleep with the infant in the adult bed than on a sofa or armchair, should the parent fall asleep. It is important to note that a large percentage of infants who die of SIDS are found with their head covered by bedding. Therefore, no pillows, sheets, blankets, or any other items that could obstruct infant breathing or cause overheating should be in the bed. Parents should also follow safe sleep recommendations outlined elsewhere in this statement. Because there is evidence that the risk of bed-sharing is higher with longer duration, if the parent falls asleep while feeding the infant in bed, the infant should be placed back on a separate sleep surface as soon as the parent awakens.

There are specific circumstances that, in case-control studies and case series, have been shown to substantially increase the risk of SIDS or unintentional injury or death while bed-sharing, and these should be avoided at all times:

- Bed-sharing with a term normal-weight infant younger than 4 months, and infants born preterm and/or with low birth weight, regardless of parental smoking status. Even for breastfed infants, there is an increased risk of SIDS when bed-sharing if younger than 4 months. This appears to be a particularly vulnerable time, so if parents choose to feed their infants younger than 4 months in bed, they should be especially vigilant to not fall asleep.
- Bed-sharing with a current smoker (even if he or she does not smoke in bed) or if the mother smoked during pregnancy.
- Bed-sharing with someone who is impaired in his or her alertness or ability to arouse because of fatigue or use of sedating medications (eg, certain antidepressants, pain medications) or substances (eg, alcohol, illicit drugs).
- Bed-sharing with anyone who is not the infant’s parent, including nonparental caregivers and other children.
- Bed-sharing on a soft surface, such as a waterbed, old mattress, sofa, couch, or armchair.
- Bed-sharing with soft bedding accessories, such as pillows or blankets.
- The safety and benefits of cobedding for twins and higher-order multiples have not been established. It is prudent to provide separate sleep surfaces and avoid cobedding for twins and higher-order multiples in the hospital and at home.

5. Keep soft objects and loose bedding away from the infant’s sleep area to reduce the risk of SIDS, suffocation, entrapment, and strangulation.

Soft objects such as pillows and pillow-like toys, quilts, comforters, sheepskins, and loose bedding such as blankets and nonfitted sheets, can obstruct an infant’s nose and mouth. An obstructed airway can pose a risk of suffocation, entrapment, or SIDS. Infant sleep clothing, such as a wearable blanket, is preferable to blankets and other coverings to keep the infant warm while reducing the chance of head covering or entrapment that could result from blanket use.

Bumper pads or similar products that attach to crib slats or sides were originally intended to prevent injury or death attributable to head entrapment. Cribs manufactured to newer standards have a narrower distance between slats to prevent...
head entrapment. Because bumper pads have been implicated as a factor contributing to deaths from suffocation, entrapment, and strangulation and because they are not necessary to prevent head entrapment with new safety standards for crib slats, they are not recommended for infants.

6. Consider offering a pacifier at nap time and bedtime.

Although the mechanism is yet unclear, studies have reported a protective effect of pacifiers on the incidence of SIDS. The protective effect of the pacifier is observed even if the pacifier falls out of the infant’s mouth.

The pacifier should be used when placing the infant for sleep. It does not need to be reinserted once the infant falls asleep. If the infant refuses the pacifier, he or she should not be forced to take it. In those cases, parents can try to offer the pacifier again when the infant is a little older.

Because of the risk of strangulation, pacifiers should not be hung around the infant’s neck. Pacifiers that attach to infant clothing should not be used with sleeping infants.

Objects, such as stuffed toys and other items that may present a suffocation or choking risk, should not be attached to pacifiers.

For breastfed infants, pacifier introduction should be delayed until breastfeeding is firmly established. Infants who are not being directly breastfed can begin pacifier use as soon as desired.

There is insufficient evidence that finger sucking is protective against SIDS.

Both maternal smoking during pregnancy and smoke in the infant’s environment after birth are major risk factors for SIDS.

Mothers should not smoke during pregnancy or after the infant’s birth.

There should be no smoking near pregnant women or infants. Encourage families to set strict rules for smoke-free homes and cars and to eliminate secondhand tobacco smoke from all places in which children and other nonsmokers spend time.

The risk of SIDS is particularly high when the infant bed-shares with an adult smoker, even when the adult does not smoke in bed.

8. Avoid alcohol and illicit drug use during pregnancy and after birth.

There is an increased risk of SIDS with prenatal and postnatal exposure to alcohol or illicit drug use.

Mothers should avoid alcohol and illicit drugs periconceptionally and during pregnancy.

Parental alcohol and/or illicit drug use in combination with bed-sharing places the infant at particularly high risk of SIDS.

9. Avoid overheating and head covering in infants.

Although studies have shown an increased risk of SIDS with overheating, the definition of overheating in these studies varies. Therefore, it is difficult to provide specific room temperature guidelines to avoid overheating.

In general, infants should be dressed appropriately for the environment, with no greater than 1 layer more than an adult would wear to be comfortable in that environment.

Parents and caregivers should evaluate the infant for signs of overheating, such as sweating or the infant’s chest feeling hot to the touch.

Overbundling and covering of the face and head should be avoided.

There is currently insufficient evidence to recommend the use of a fan as a SIDS risk-reduction strategy.

10. Pregnant women should obtain regular prenatal care.

There is substantial epidemiologic evidence linking a lower risk of SIDS for infants whose mothers obtain regular prenatal care. Pregnant women should follow guidelines for frequency of prenatal visits.

11. Infants should be immunized in accordance with recommendations of the AAP and Centers for Disease Control and Prevention.

There is no evidence that there is a causal relationship between immunizations and SIDS. Indeed, recent evidence suggests that vaccination may have a protective effect against SIDS.

12. Avoid the use of commercial devices that are inconsistent with safe sleep recommendations.

Be particularly wary of devices that claim to reduce the risk of SIDS. Examples include, but are not limited to, wedges and positioners and other devices placed in the adult bed for the purpose of positioning or separating the infant from others in the bed.

Crib mattresses also have been developed to improve the dispersion of carbon dioxide in the event that the infant ends up in the prone position during sleep. Although data do not support the claim of carbon dioxide dispersion unless there is an active dispersal component, there is no harm in using these mattresses if they meet standard safety requirements. However, there is no evidence that any of these devices reduce the risk of SIDS. Importantly, the use of products claiming to increase sleep safety does not diminish the importance of following recommended safe sleep practices. Information about a specific product can be found on the CPSC Web site (www.cpsc.gov). The AAP concurs with the US Food and Drug Administration and the CPSC that manufacturers should not claim that a product or device protects against SIDS unless there is scientific evidence to that effect.

13. Do not use home cardiorespiratory monitors as a strategy to reduce the risk of SIDS.

The use of cardiorespiratory monitors has not been documented.
to decrease the incidence of SIDS. These devices are sometimes prescribed for use at home to detect apnea or bradycardia and, when pulse oximetry is used, decreases in oxyhemoglobin saturation for infants at risk of these conditions. In addition, routine in-hospital cardiorespiratory monitoring before discharge from the hospital has not been shown to detect infants at risk of SIDS. There are no data that other commercial devices that are designed to monitor infant vital signs reduce the risk of SIDS.

14. Supervised, awake tummy time is recommended to facilitate development and to minimize development of positional plagiocephaly.

Although there are no data to make specific recommendations as to how often and how long it should be undertaken, the task force concurs with the AAP Committee on Practice and Ambulatory Medicine and Section on Neurologic Surgery that “a certain amount of prone positioning, or ‘tummy time,’ while the infant is awake and being observed is recommended to help prevent the development of flattening of the occiput and to facilitate development of the upper shoulder girdle strength necessary for timely attainment of certain motor milestones.”

Diagnosis, management, and other prevention strategies for positional plagiocephaly, such as avoidance of excessive time in car seats and changing the infant’s orientation in the crib, are discussed in detail in the AAP clinical report on positional skull deformities.

15. There is no evidence to recommend swaddling as a strategy to reduce the risk of SIDS.

Swaddling, or wrapping the infant in a light blanket, is often used as a strategy to calm the infant and encourage the use of the supine position. There is a high risk of death if a swaddled infant is placed in or rolls to the prone position. If infants are swaddled, they should always be placed on the back. Swaddling should be snug around the chest but allow for ample room at the hips and knees to avoid exacerbation of hip dysplasia. When an infant exhibits signs of attempting to roll, swaddling should no longer be used.

There is no evidence with regard to SIDS risk related to the arms swaddled in or out. These decisions about swaddling should be made on an individual basis, depending on the physiologic needs of the infant.

16. Health care professionals, staff in newborn nurseries and NICUs, and child care providers should endorse and model the SIDS risk-reduction recommendations from birth.

Staff in NICUs should model and implement all SIDS risk-reduction recommendations as soon as the infant is medically stable and well before anticipated discharge.

Staff in newborn nurseries should model and implement these recommendations beginning at birth and well before anticipated discharge.

All physicians, nurses, and other health care providers should receive education on safe infant sleep. Health care providers should screen for and recommend safe sleep practices at each visit for infants up to 1 year old. Families who do not have a safe sleep space for their infant should be provided with information about low-cost or free cribs or play yards.

Hospitals should ensure that hospital policies are consistent with updated safe sleep recommendations and that infant sleep spaces (bassinets, cribs) meet safe sleep standards.

All state regulatory agencies should require that child care providers receive education on safe infant sleep and implement safe sleep practices. It is preferable that they have written policies.

17. Media and manufacturers should follow safe sleep guidelines in their messaging and advertising.

Media exposures (including movie, television, magazines, newspapers, and Web sites), manufacturer advertisements, and store displays affect individual behavior by influencing beliefs and attitudes. Media and advertising messages contrary to safe sleep recommendations may create misinformation about safe sleep practices.

18. Continue the “Safe to Sleep” campaign, focusing on ways to reduce the risk of all sleep-related infant deaths, including SIDS, suffocation, and other unintentional deaths.

Pediatricians and other primary care providers should actively participate in this campaign.

Public education should continue for all who care for infants, including parents, child care providers, grandparents, foster parents, and babysitters, and should include strategies for overcoming barriers to behavior change.

The campaign should continue to have a special focus on the black and American Indian/Alaskan Native populations because of the higher incidence of SIDS and other sleep-related infant deaths in these groups.

The campaign should specifically include strategies to increase breastfeeding while decreasing bed-sharing, and eliminating tobacco smoke exposure. The campaign should also highlight the circumstances that substantially increase the risk of SIDS or unintentional injury or death while bed-sharing, as listed previously.

These recommendations should be introduced before pregnancy and ideally in secondary school curricula to both males and females and incorporated into courses developed to train teenaged and adult babysitters. The importance
of maternal preconceptional health, infant breastfeeding, and the avoidance of substance use (including alcohol and smoking) should be included in this training.

Safe sleep messages should be reviewed, revised, and reissued at least every 5 years to address the next generation of new parents and products on the market.

19. 

Continue research and surveillance on the risk factors, causes, and pathophysiologic mechanisms of SIDS and other sleep-related infant deaths, with the ultimate goal of eliminating these deaths altogether.

Education campaigns need to be evaluated, and innovative intervention methods need to be encouraged and funded.

Continued research and improved surveillance on the etiology and pathophysiologic basis of SIDS should be funded.

Standardized protocols for death scene investigations, as per Centers for Disease Control and Prevention protocol, should continue to be implemented. Comprehensive autopsies, including full external and internal examination of all major organs and tissues including the brain; complete radiographs; metabolic testing; and toxicology screening should be performed. Training about how to conduct a comprehensive death scene investigation offered to medical examiners, coroners, death scene investigators, first responders, and law enforcement should continue; and resources to maintain training and conduct of these investigations need to be allocated. In addition, child death reviews, with involvement of pediatricians and other primary care providers, should be supported and funded.

Improved and widespread surveillance of SIDS and SUID cases should be implemented and funded.

Federal and private funding agencies should remain committed to all aspects of the aforementioned research.

ACKNOWLEDGMENTS

We acknowledge the contributions provided by others to the collection and interpretation of data examined in preparation of this report. We are particularly grateful for the independent biostatistical report submitted by Robert W. Platt, PhD.
